1. Motivations and objectives

Climate change: current evidences

- Global mean surface air temperature has risen by about 0.74°C (1906-2005)
- 11 of the 12 warmest years on record have occurred in the past 12 years
- Important regional variations
- Redistribution of rainfall and other variables

Extreme weather events

Summary for Policymakers (IPCC)

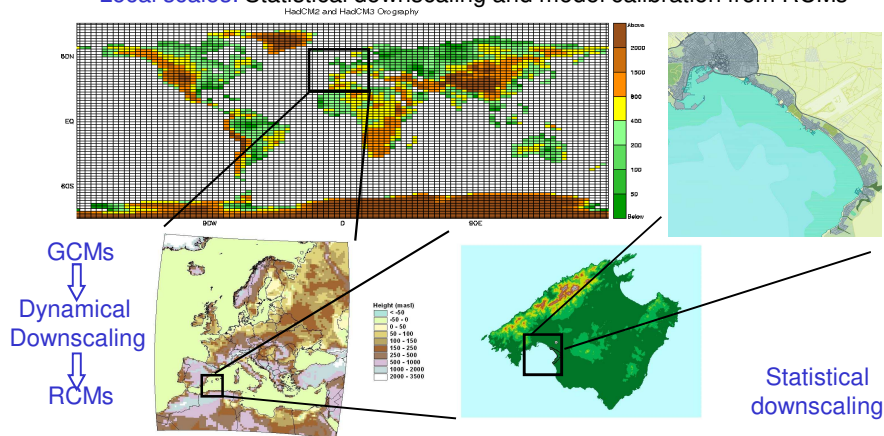

- ↓ cold days and nights (99%)
- ↑ hot days and nights (99%)
- ↑ frequent and/or intense heavy rainfall events (90%) Longer and/or more intense droughts (66%)
- ↑ hurricane activity (50%) (western north pacific and north atlantic)

Tools for exploring climate change impacts

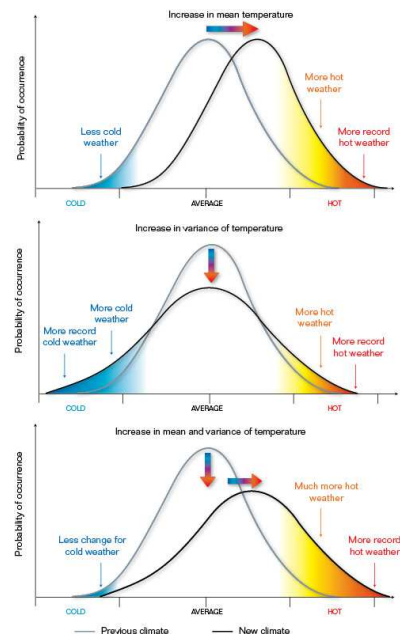

- GCMs → RCMs

-**Regional scales:** Dynamical downscaling. Regional Climate Models (RCMs)

-**Local scales:** Statistical downscaling and model calibration from RCMs

Statistical downscaling of RCM outputs

Statistical downscaling of RCM outputs: Quantile-Quantile adjustment (Amengual et al. 2012)

$$p_i = o_i + g\bar{\Delta} + f\Delta'_i,$$

$$\Delta_i = s_{fi} - s_{ci}$$

$$\bar{\Delta} = \frac{\sum_{i=1}^N \Delta_i}{N} = \frac{\sum_{i=1}^N (s_{fi} - s_{ci})}{N} = \bar{s}_f - \bar{s}_c$$

$$\Delta'_i = \Delta_i - \bar{\Delta} \quad g = \frac{\left(\sum_{i=1}^N o_i\right) / N}{\left(\sum_{i=1}^N s_{ci}\right) / N} = \frac{\bar{o}}{\bar{s}_c}$$

$$f = \frac{\sigma_o}{\sigma_{s_c}} = \frac{\text{IQR}|_o}{\text{IQR}|_{s_c}}$$

Global

$$f = \frac{\sigma_{oi}}{\sigma_{s_{ci}}}$$

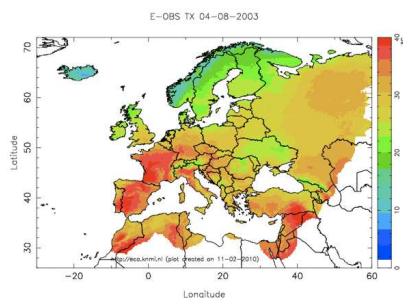

Local

2. Database and methodology

E-OBS gridded dataset (25 km)

EURO-CORDEX (12,5 km)

Validation task

Evaluation of raw and calibrated data compared against observations for the 1956-1980 interval. Control period (1981-2005)

Climate change projections

Compute changes in calibrated CDFs between a 25-year past (i.e. control/observed; 1981-2005) and successive 25-year RCM time-slices (2021-2045; 2046-2070; **2071-2095**)

Future regional scenario
rcp4.5 and **rcp8.5**

Extreme weather events

1. Heat Waves
2. Cold Spells
3. Heavy precipitation
4. Droughts

We characterize their attributes with the following parameters:

- Number of extreme events that occur in a given time interval
- Frequency: the number of days under extreme conditions in a given time interval
- Duration exceedance: the total number of consecutive days exceeding the duration threshold for all events in a given time interval. It accounts for the whole amount of excess days.
- Amplitude exceedance: the accumulated thermal stress exceedance for all the days under extreme conditions in a given time interval.

3. Results

3.1 Heat waves

- A spell lasting $d_{th} = 3$ or more consecutive days with *daily maximum temperature* above 95th percentile of observed daily maximum temperature in summer.

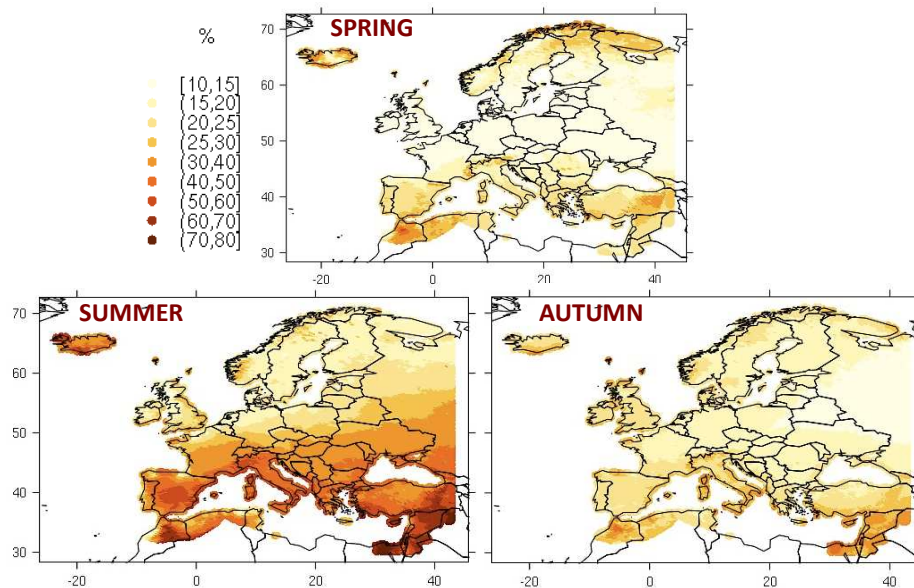

Fig. 1. Graphical sketch of heat wave duration (HWD) and amplitude (HWA, gray shading) exceedances. T_{th} and d_{th} denote the thermal stress and duration thresholds, respectively.

Events over P95 of daily maximum temperature

3. Results

3.2 Cold spells

- A spell lasting $d_{th} = 3$ or more consecutive days with *daily minimum temperature* under 5th percentile of observed daily minimum temperature in winter.

➤ Future events under P5 of daily observed minimum temperature in winter.

➤ Cold Spell Amplitude (CSA)

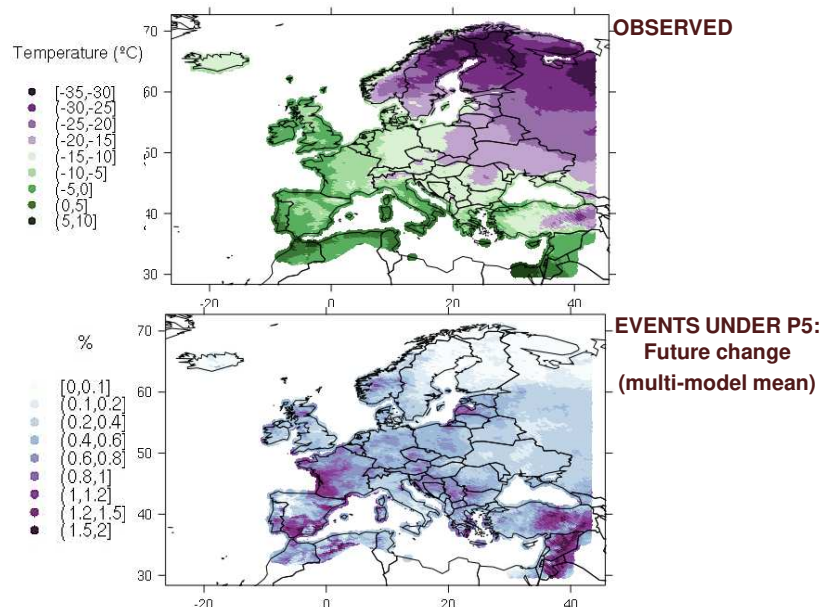

$$CSA = T_{th} \text{ CSF} - CST$$

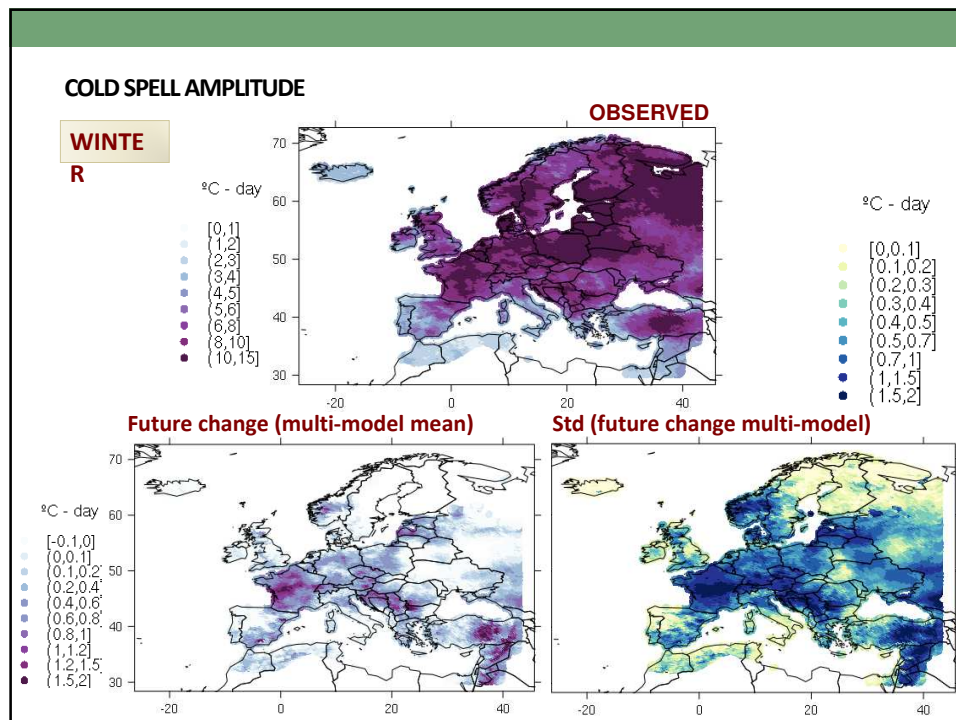

T_{th} : thermal stress

CSF: cold spell frequency

CST: integral of the minimum daily temperatures over the duration of each individual cold spell, and accumulated for all cold spells in a given time interval

P5 of daily minimum temperature (WINTER)

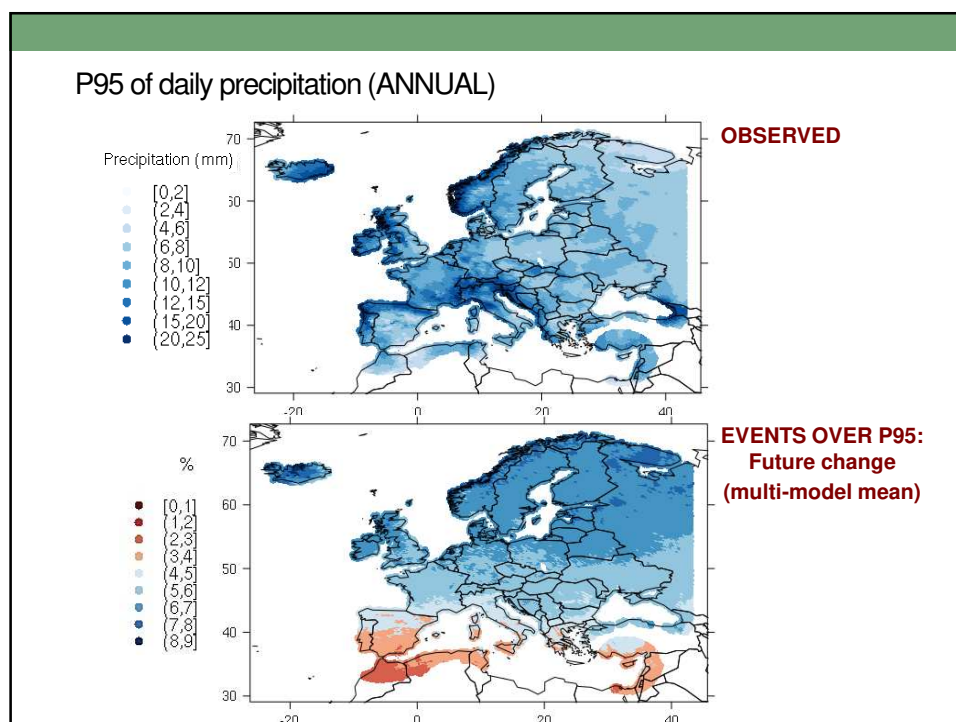

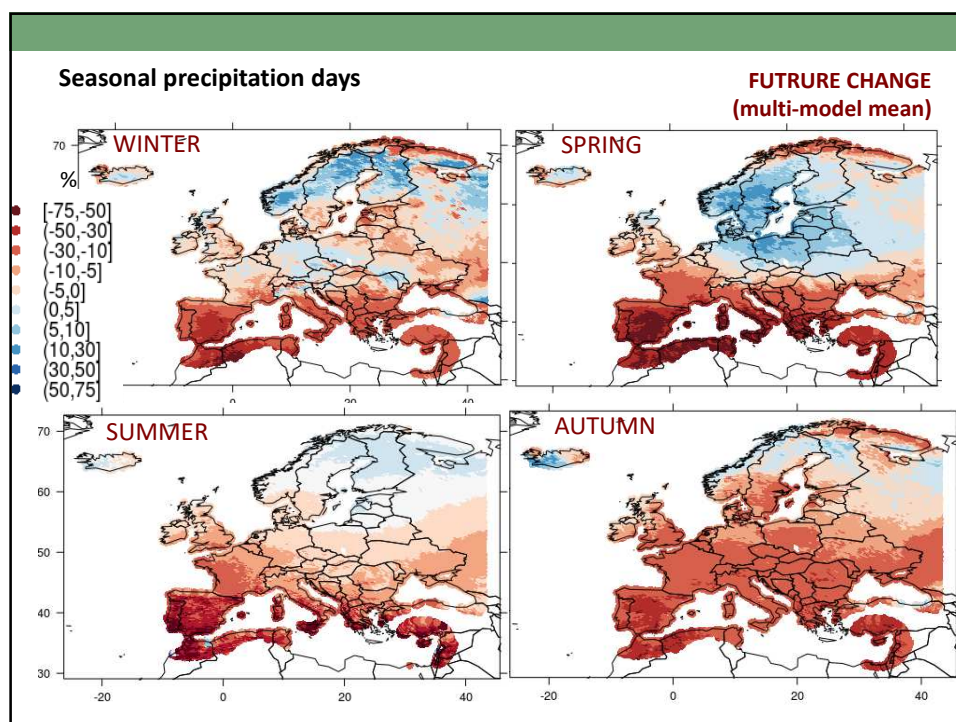

3. Results

3.3 Heavy precipitation

- A spell lasting $dth = 2$ or more consecutive days with *daily precipitation* ≥ 0.01 mm

- Future change in seasonal precipitation days.
- Future events over P95 of daily annual observed precipitation.
- Heavy Precipitation Amplitude (HPA)

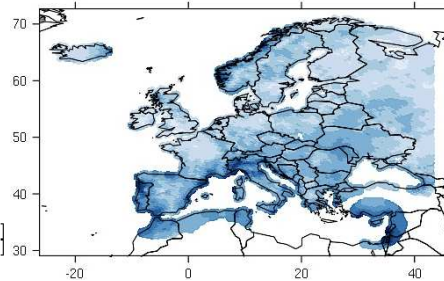

$$HPA = HPT - Tth \text{ HPF}$$
